# **CSE 311: Computer Networks**

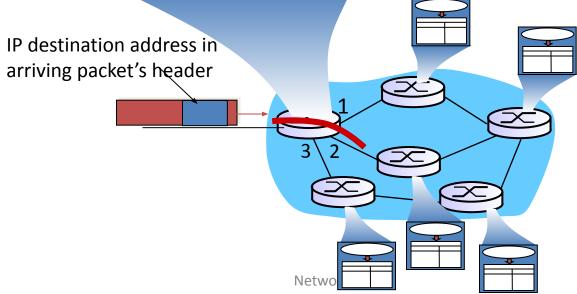

Network Layer

## Interplay between routing, forwarding

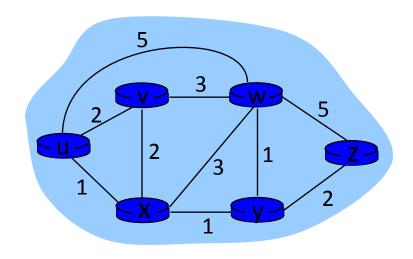

routing algorithm determines end-end-path through network

forwarding table determines local forwarding at this router

# **Graph abstraction**

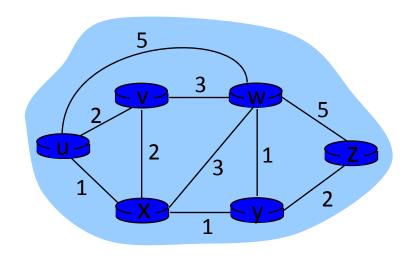

**graph: G** = **(N,E)** 

**N** = set of routers = { u, v, w, x, y, z }

 $E = set of links = \{ (u,v), (u,x), (v,x), (v,w), (x,w), (x,y), (w,y), (w,z), (y,z) \}$ 

# Graph abstraction: costs

$$c(x,x') = cost of link (x,x')$$
  
e.g.,  $c(w,z) = 5$ 

cost of path 
$$(x_1, x_2, x_3, ..., x_p) = c(x_1, x_2) + c(x_2, x_3) + ... + c(x_{p-1}, x_p)$$

**key question:** what is the least-cost path between u and z ? **routing algorithm:** algorithm that finds that least cost path

## Routing algorithm classification

# Q: global or decentralized information?

### global:

- all routers have complete topology, link cost info
- "link state" algorithms

#### decentralized:

- router knows physically-connected neighbors, link costs to neighbors
- iterative process of computation, exchange of info with neighbors
- "distance vector" algorithms

### Q: static or dynamic?

#### static:

routes change slowly over time

### dynamic:

- routes change more quickly
  - periodic update
  - in response to link cost changes

### A Link-State Routing Algorithm

### Dijkstra's algorithm

- net topology, link costs known to all nodes
  - accomplished via "link state broadcast"
  - all nodes have same info
- computes least cost paths from one node ('source") to all other nodes
  - gives forwarding table for that node
- iterative: after k
   iterations, know least cost
   path to k dest.'s

#### notation:

- C(X,y): link cost from node x to y; = ∞ if not direct neighbors
- D(V): current value of cost of path from source to dest.
- p(V): predecessor node along path from source to v
- N': set of nodes whose least cost path definitively known

## Dijsktra's Algorithm

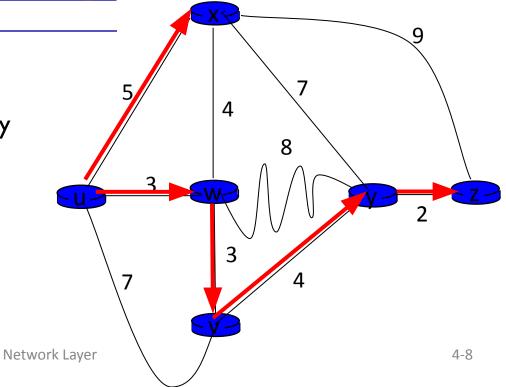

```
1 Initialization:
   N' = \{u\}
   for all nodes v
    if v adjacent to u
       then D(v) = c(u,v)
5
    else D(v) = \infty
6
7
  Loop
    find w not in N' such that D(w) is a minimum
10 add w to N'
    update D(v) for all v adjacent to w and not in N':
      D(v) = \min(D(v), D(w) + c(w,v))
    /* new cost to v is either old cost to v or known
     shortest path cost to w plus cost from w to v */
15 until all nodes in N'
```

# Dijkstra's algorithm: example

		D( <b>v</b> )	D(w)	D(x)	D(y)	D(z)
Step	N'	p(v)	p(w)	p(x)	p(y)	p(z)
0	u	7,u	3,u	5,u	∞	∞
1	uw	6,w		5,u	11,W	∞
2	uwx	6,w			11,W	14,x
3	uwxv			(	10,	14,x
4	uwxvy					12,
5	uwxvyz					

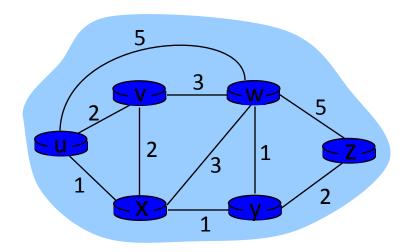

#### notes:

- construct shortest path tree by tracing predecessor nodes
- ties can exist (can be broken arbitrarily)

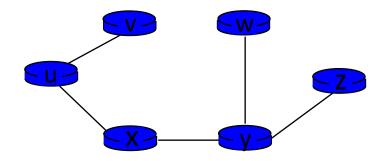

# Dijkstra's algorithm: another example

Step	N'	D(v),p(v)	D(w),p(w)	D(x),p(x)	D(y),p(y)	D(z),p(z)
0	u	2,u	5,u	1,u	∞	∞
1	ux <del>-</del>	2,u	4,x		2,x	∞
2	uxy	<del>2,</del> u	3,y			4,y
3	uxyv		3,y			4,y
4	uxyvw ←					4,y
5	uxyvwz <del>-</del>					

## Dijkstra's algorithm: example (2)

resulting shortest-path tree from u:

### resulting forwarding table in u:

destination	link
V	(u,v)
X	(u,x)
У	(u,x)
W	(u,x)
Z	(u,x)
	Network
